Abstract

This article aimed to study: (1) the concept of mental healing from the Buddhist perspective, (2) the integration of Buddhist principles with contemporary mental health care, and (3) the synthesis of an integrative Buddhist model of mental healing for mental health care. The research employed a qualitative methodology, drawing on Buddhist philosophy and holistic healing theories as the research framework. The research area focused on documentary studies and related research on Buddhist approaches to mental healing. The target sources comprised 45 academic documents and research articles published between 2018 and 2023, selected through purposive sampling. The research instruments included: (1) a document analysis form, (2) an expert interview form, and (3) a credibility verification form. Data were analyzed using content analysis and conceptual synthesis, and findings were presented in descriptive narrative form.

The research results revealed the following. 1. Buddhist mental healing is grounded in the Four Noble Truths and the Noble Eightfold Path, emphasizing the understanding of the nature of suffering and the path to liberation. 2. The integration of Buddhist principles with mental health care enhances the effectiveness of healing through mindfulness practice, the cultivation of wisdom, and the reframing of perspectives. 3. The integrative Buddhist mental healing model consists of five key components: mindfulness (sati), wisdom (paññā), loving-kindness (mettā), concentration (samādhi), and perseverance (viriya). The study proposes an integrative Buddhist mental healing model that can be applied to holistic mental health care and serves as a guideline for developing healing innovations aligned with the Thai socio-cultural context

Keywords: Mental healing, Buddhism, Mental health, Buddhist integration

Introduction

Mental health has emerged as one of the most pressing global health challenges of the twenty-first century. The World Health Organization (2022) reports that mental disorders affect a significant proportion of the global population, with depression and anxiety disorders representing the leading causes of disability worldwide. In Thailand, the Department of Mental Health (2023) documented a notable rise in mental health consultations and psychiatric hospitalizations in recent years. Despite advances in pharmacological and psychotherapeutic treatments, significant gaps remain in achieving sustainable, culturally congruent mental well-being, particularly in Asian societies where spiritual and religious dimensions of health are deeply embedded in daily life. This situation calls for innovative approaches that bridge evidence-based mental health care with traditional wisdom systems.

Buddhism, as a philosophical and spiritual tradition with over 2,500 years of history, offers a profound framework for understanding the human mind and alleviating psychological suffering. The Buddha's teachings center on the nature of suffering (dukkha), its causes, and pathways to its cessation, which align remarkably with contemporary understandings of psychological distress. Attarung (2023) demonstrated that Buddhist principles, particularly the Four Noble Truths and the Noble Eightfold Path, provide a systematic approach to mind healing that complements and enriches modern mental health care. Scholars such as Kabat-Zinn (2019) and Goleman and Davidson (2020) have shown that practices derived from Buddhist traditions, including mindfulness-based stress reduction (MBSR) and mindfulness-based cognitive therapy (MBCT), produce measurable improvements in psychological well-being. Nevertheless, the deeper integration of Buddhist wisdom—beyond mindfulness techniques—into clinical practice remains an underexplored territory.

The present article seeks to address this gap by systematically examining how Buddhist wisdom can be integrated into mental health care for the purpose of mind healing. This study employs a qualitative, documentary research methodology and draws on a range of Buddhist texts, contemporary psychology, and integrative health literature. The article is organized as follows: it first reviews the conceptual foundations of Buddhist mental healing; second, it analyzes mechanisms of integration between Buddhist principles and mental health care; and third, it synthesizes a practical, five-component model of integrative Buddhist mental healing. It is hoped that this contribution will support mental health practitioners, policymakers, and researchers in developing culturally sensitive and holistically grounded approaches to mind care.

Research Objectives

1. To examine the concept of mental healing from the Buddhist perspective.
2. To analyze the integration of Buddhist principles with contemporary mental health care.
3. To synthesize an integrative Buddhist model of mental healing for mental health care.

Literature Review

1. Buddhist Foundations of Mental Healing. Buddhist teachings have long addressed the psychological dimensions of human experience. The Pali Canon presents a sophisticated account of mental phenomena (cetasika) and their relationship to suffering and liberation. The Four Noble Truths—the truth of suffering (dukkha), its origin (samudaya), its cessation (nirodha), and the path to cessation (magga)—constitute a therapeutic framework that anticipates many elements of modern cognitive and behavioral therapies (Saipetch, 2023). Central to Buddhist mental healing is the cultivation of insight (vipassanā) into the three characteristics of existence: impermanence (anicca), suffering (dukkha), and non-self (anattā). According to Attarung (2023), recognizing these characteristics reduces attachment and reactivity, which are primary sources of psychological distress.

2. Contemporary Integration of Buddhist Practices in Mental Health. The past three decades have witnessed growing scientific interest in Buddhist-derived interventions. Kabat-Zinn (2019) pioneered MBSR, demonstrating its efficacy in reducing stress, anxiety, and chronic pain. Williams et al. (2022) established MBCT as an evidence-based approach for preventing relapse in recurrent depression. Hayes et al. (2022) developed acceptance and commitment therapy (ACT), which incorporates mindfulness and acceptance processes aligned with Buddhist concepts of non-attachment and present-moment awareness. These developments confirm the clinical relevance of Buddhist principles, though they represent partial applications rather than comprehensive integration of the Buddhist healing system.

3. Knowledge Gaps. Despite this body of evidence, the majority of existing literature focuses narrowly on mindfulness meditation while neglecting other equally important elements of Buddhist teaching, such as loving-kindness (mettā), wisdom cultivation (paññā), ethical living (sīla), and mental concentration (samādhi). Moreover, cultural contextualization—particularly within the Thai Buddhist context—remains limited. Kittinannik (2023) and Srisuk (2022) highlighted that the effectiveness of Buddhist interventions may be enhanced when they are culturally embedded and delivered within familiar spiritual contexts.

The present study addresses these gaps by proposing a comprehensive, culturally grounded model of integrative Buddhist mental healing.

In summary, the literature consistently affirms the therapeutic potential of Buddhist teachings while revealing the need for more holistic and culturally situated models of integration. This study employs the Five Aggregates (khandhas) theory and the Noble Eightfold Path as its primary theoretical framework, as these offer the most comprehensive account of mind and its transformation.

Conceptual Framework

This study is a qualitative documentary research. The researcher formulated the research framework based on the theoretical constructs of Buddhist philosophy—specifically the Four Noble Truths, the Noble Eightfold Path, and the Five Aggregates (khandhas)—integrated with contemporary psychological healing models including MBSR, MBCT, and ACT. The independent variable consists of Buddhist principles and practices (mindfulness, wisdom, loving-kindness, concentration, and perseverance). The process involves integrative analysis and expert consultation. The dependent variable is the proposed integrative Buddhist mental healing model applicable to mental health care settings.

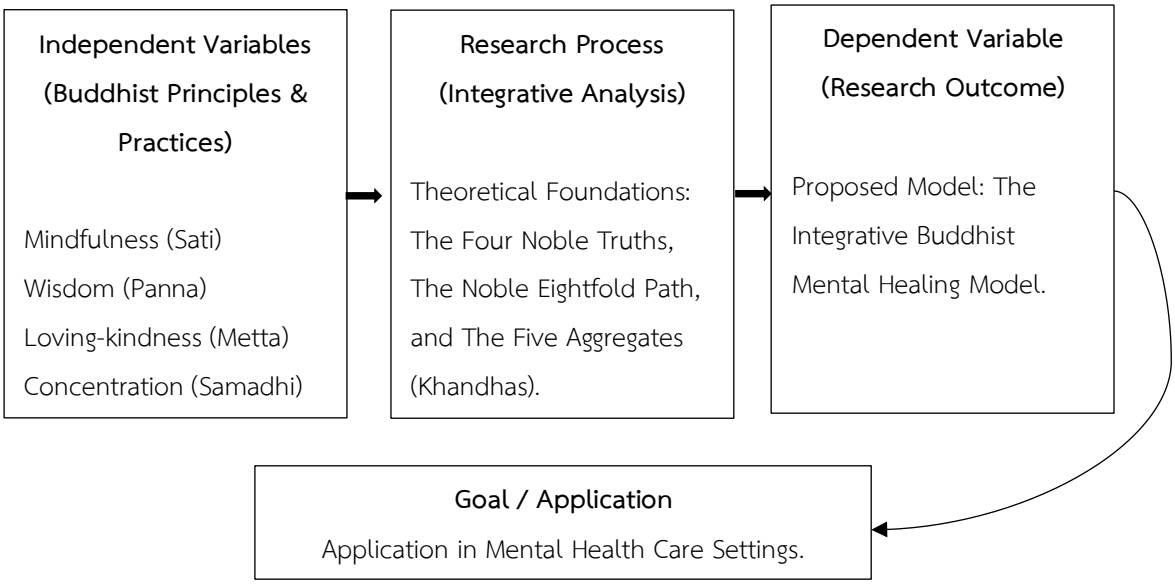

Figure 1. Research Framework for Integrating Buddhist Wisdom into Mental Health Care

Research Methodology

Population and Sample

The population for this study comprised all academic documents, research articles, Buddhist texts, and expert opinions related to Buddhist approaches to mental healing. The sample consisted of 45 purposively selected documents published between 2018 and 2023, including peer-reviewed articles, Buddhist canonical texts and commentaries, textbooks in psychiatry and psychology, and official reports from health authorities. Purposive sampling was employed to ensure that selected sources directly addressed the intersection of Buddhist teaching and mental health care and met predefined quality criteria.

Research Instruments

Three instruments were developed and validated for this study. First, a document analysis form was used to systematically extract and record relevant information from selected documents, covering theoretical frameworks, key concepts, methodological approaches, and findings. Second, an expert interview form was designed to elicit insights from five specialists in Buddhist studies, clinical psychology, and integrative health, using semi-structured interview questions. Third, a credibility verification form was employed to assess the accuracy and trustworthiness of synthesized content, submitted to three independent expert reviewers.

Data Collection

Data collection proceeded in three stages. In the first stage, relevant documents were identified through systematic database searches in TCI Thai-Jo, PubMed, PsycINFO, and Google Scholar using keywords such as “Buddhist mental health,” “mindfulness therapy,” “Buddhist integration,” and “mind healing.” In the second stage, expert interviews were conducted individually with five specialists between January and March 2024, each lasting approximately 60 to 90 minutes, recorded with participants’ consent. In the third stage, synthesized findings were submitted for expert verification and credibility assessment.

Data Analysis

Data were analyzed using content analysis and conceptual synthesis. Document data were coded thematically, with categories derived deductively from the research objectives and inductively from emergent patterns in the data. Interview transcripts were subjected to thematic analysis following Braun and Clarke’s (2006) framework. Triangulation was achieved by cross-referencing documentary evidence, expert interview data, and existing theoretical models. The synthesized model was subsequently verified by the expert panel for content validity and practical applicability.

Research Results

Objective 1: Buddhist Perspectives on Mental Healing The documentary analysis revealed that Buddhist mental healing is fundamentally grounded in the Four Noble Truths (ariyasacca) and the Noble Eightfold Path (aṭṭhangika-magga). The First Noble Truth—the acknowledgment of suffering (dukkha)—parallels the diagnostic function in clinical psychology: recognizing and naming psychological distress as the essential first step toward healing. The Second Noble Truth identifies craving (tanhā) and attachment (upādānа) as the primary causes of mental anguish, which resonates with cognitive-behavioral models attributing distress to maladaptive thought patterns and emotional dysregulation. The Third Noble Truth affirms the possibility of liberation (nibbāna), providing a vision of psychological wholeness analogous to the concept of mental health recovery. The Fourth Noble Truth prescribes the Noble Eightfold Path as the systematic route to liberation.

Expert interviews corroborated these findings. All five informants emphasized that Buddhist teaching offers a comprehensive diagnostic and therapeutic system for the mind, rooted in experiential practice rather than abstract philosophy. One expert noted that the Eightfold Path functions as a holistic lifestyle prescription encompassing cognitive (right view, right intention), behavioral (right speech, right action, right livelihood), and meditative (right effort, right mindfulness, right concentration) dimensions of mental health. This multidimensional structure distinguishes the Buddhist approach from symptom-focused biomedical models and positions it as a genuinely integrative framework for mind healing.

Objective 2: Integration of Buddhist Principles with Mental Health Care The analysis identified three principal mechanisms through which Buddhist principles enhance mental health care. First, mindfulness practice (sati-sampajjañña) cultivates present-moment awareness and non-reactive observation of thoughts and emotions. Santorelli et al. (2023) documented that MBSR programs based on Buddhist mindfulness significantly reduce anxiety, depression, and stress-related physiological arousal. Second, wisdom cultivation (paññā-bhāvanā) enables clients to develop insight into the impermanent, interdependent nature of their distress, reducing catastrophizing and promoting cognitive flexibility. Third, perspective reframing through the lens of the Three Characteristics of Existence (tilakkhaṇa) provides a transformative conceptual framework for interpreting adversity, loss, and psychological pain. Harris (2023) and Hayes et al. (2022) similarly described how acceptance-based processes grounded in non-attachment reduce the intensity of psychological suffering.

Expert informants highlighted that integration is most effective when Buddhist practices are not merely transplanted into clinical settings but are embedded within

meaningful cultural and spiritual contexts. In the Thai context, where Theravada Buddhism permeates daily social life, incorporating dharma teachings, chanting, merit-making, and monastic counseling into mental health programs was reported to significantly enhance patient engagement and treatment adherence. Saipetch (2023) confirmed that Buddhist-integrated mental health programs in Thai community settings achieved superior outcomes on measures of well-being and relapse prevention compared to standard care alone.

Objective 3: Integrative Buddhist Mental Healing Model Synthesizing documentary evidence and expert insights, the researcher proposes an Integrative Buddhist Mental Healing (IBMH) Model comprising five interdependent components. Component 1: Mindfulness (sati)—systematic cultivation of present-moment, non-judgmental awareness as the foundational practice of mental healing, operationalized through breath meditation, body scanning, and mindful daily activities. Component 2: Wisdom (paññā)—progressive development of insight into the impermanent and interdependent nature of mental phenomena, reducing the power of rumination and cognitive fusion. Component 3: Loving-kindness (mettā)—deliberate cultivation of benevolent compassion toward oneself and others, countering shame, self-criticism, and interpersonal hostility, as supported by Srisuk (2022). Component 4: Concentration (samādhi)—development of sustained attentional stability and mental tranquility through progressive meditation, reducing intrusive thoughts and emotional dysregulation. Component 5: Perseverance (viriya)—cultivation of diligent, sustained effort in practice, underpinning the consistency required for long-term psychological change.

These five components are not independent modules but mutually reinforcing elements of a unified healing process. The IBMH Model is designed to be implemented in a sequential yet flexible manner, beginning with mindfulness as the entry point and progressively incorporating wisdom, loving-kindness, concentration, and perseverance as the practitioner's capacity deepens. The model can be adapted for individual therapy, group programs, and community-level interventions.

Discussion

Objective 1 Results. The finding that Buddhist mental healing is grounded in the Four Noble Truths and the Noble Eightfold Path aligns with the seminal work of Attarung (2023), who demonstrated the structural parallels between the Buddha's diagnostic-prescriptive teaching and contemporary psychotherapeutic frameworks. This convergence may be explained by the shared epistemological commitment of both Buddhist teaching and

psychological science to understanding the causes of suffering and systematically alleviating them. Dhammapitaka (2023) similarly argued that Buddhist psychology (Abhidharma) constitutes a sophisticated science of the mind that predates and parallels modern psychiatry. This finding supports the call for greater recognition of non-Western healing traditions within integrative medicine and mental health care.

Objective 2 Results. The identification of mindfulness, wisdom cultivation, and perspective reframing as the key mechanisms of integration supports and extends existing theoretical models. Goleman and Davidson (2020) documented that long-term meditation practice produces structural changes in brain regions associated with emotional regulation and self-referential processing. The present study adds to this literature by demonstrating that cultural embeddedness is a critical moderating variable in the effectiveness of Buddhist-integrated mental health care. Specifically, in Buddhist societies such as Thailand, spiritual context amplifies the therapeutic impact of mindfulness and wisdom practices, as participants can draw on pre-existing religious knowledge and community support structures. This finding resonates with the cultural competence literature, which consistently shows that culturally sensitive interventions outperform culturally neutral ones.

Objective 3 Results. The five-component IBMH Model represents a meaningful advance over existing partial integration models. Unlike MBSR or MBCT, which focus primarily on mindfulness, the IBMH Model incorporates the full spectrum of Buddhist mental cultivation, providing a more comprehensive therapeutic architecture. The inclusion of loving-kindness (mettā) is particularly significant, given Srisuk's (2022) evidence that loving-kindness meditation reduces anger, self-criticism, and interpersonal hostility—factors strongly implicated in affective disorders. The emphasis on perseverance (viriya) reflects the recognition that sustainable mental health recovery requires sustained effort and motivation, addressing a common challenge in long-term therapeutic engagement. Future validation studies should test the IBMH Model in randomized controlled trials across different clinical populations and cultural settings.

New Knowledge Generated from the Research

The primary contribution of this research is the Integrative Buddhist Mental Healing (IBMH) Model, a theoretically grounded, culturally situated five-component framework for incorporating Buddhist wisdom into mental health care. The model addresses the knowledge gap identified in the literature by providing a comprehensive, operationalizable structure that goes beyond mindfulness to include wisdom, loving-kindness, concentration, and

perseverance. This framework can guide the development of structured Buddhist-integrated mental health programs, training curricula for clinicians and counselors working in Buddhist contexts, and policy frameworks for holistic mental health care in Thailand and other Buddhist societies. The model may be visually conceptualized as a five-petal lotus flower, where each petal represents one component, all arising from and returning to the central "mind" (citta), symbolizing the interdependence and wholeness of the healing process.

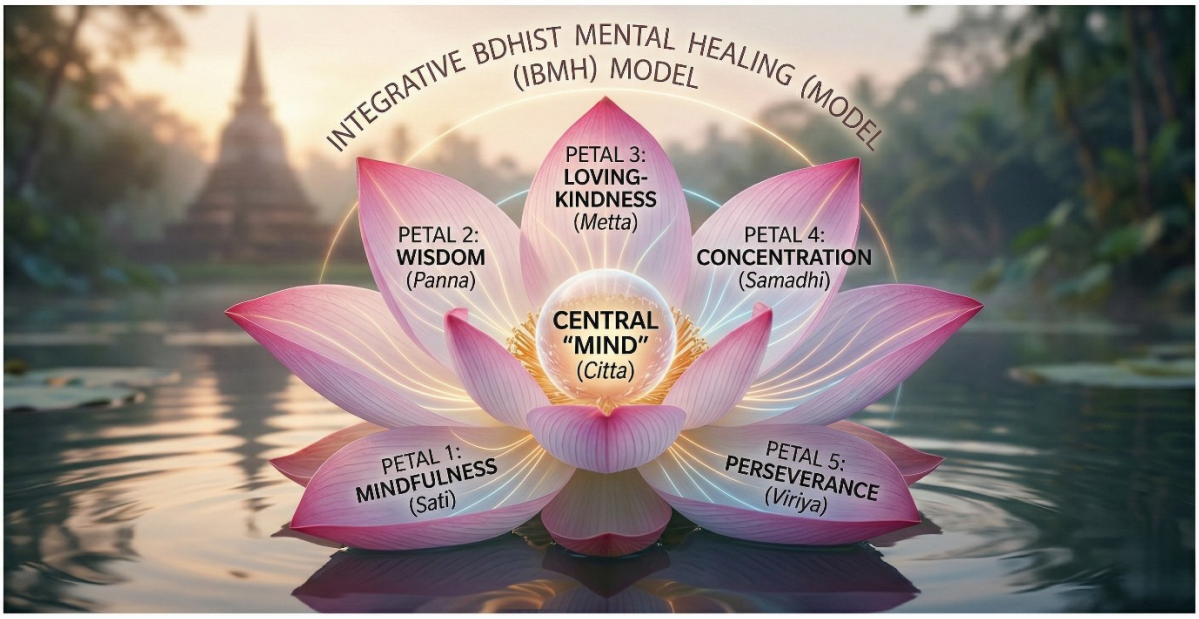

Figure 2: Integrative Buddhist Mental Healing (IBMH) Model

Conclusion

This article has examined the integration of Buddhist wisdom into mental health care for mind healing through a systematic qualitative documentary study. The research demonstrated that Buddhist mental healing—rooted in the Four Noble Truths and the Noble Eightfold Path—offers a philosophically coherent and practically effective framework for addressing psychological suffering. The integration of Buddhist principles into mental health care operates through mindfulness practice, wisdom cultivation, and perspective reframing, and is most effective when delivered within culturally congruent contexts. The synthesized Integrative Buddhist Mental Healing (IBMH) Model, comprising mindfulness (sati), wisdom (paññā), loving-kindness (mettā), concentration (samādhi), and perseverance (viriya), provides a comprehensive and actionable framework for holistic mind healing. This study affirms the value of engaging ancient contemplative traditions as genuine knowledge systems in the pursuit of mental health equity and cultural responsiveness in care.

Recommendations

1. Recommendations for Applying the Research Findings

Objective 1 finding: Buddhist mental healing is grounded in the Four Noble Truths and Noble Eightfold Path. Relevant agencies, including the Department of Mental Health and mental health hospitals, should incorporate Buddhist-informed psychoeducation into patient orientation programs and community mental health promotion campaigns.

Objective 2 finding: Buddhist principles enhance mental health care effectiveness through mindfulness, wisdom, and perspective reframing. Mental health practitioners should receive training in Buddhist-informed therapeutic techniques, and clinical guidelines should be developed for their systematic application alongside evidence-based treatments.

Objective 3 finding: The five-component IBMH Model provides a comprehensive integrative framework. Health care institutions and Buddhist organizations should collaborate to pilot and evaluate IBMH-based programs in outpatient psychiatric clinics, rehabilitation centers, and community temples, with particular attention to populations at risk of depression, anxiety, and adjustment disorders.

2. Recommendations for Future Research

The key finding of this research—the IBMH Model—can be applied to a wide range of clinical and community mental health contexts. Future research should: (1) conduct randomized controlled trials to empirically validate the IBMH Model with specific clinical populations such as individuals with depressive disorder, anxiety disorder, and post-traumatic stress disorder; (2) develop and validate standardized IBMH program protocols and assessment tools; (3) explore cross-cultural adaptations of the model for non-Buddhist populations; and (4) investigate neurobiological correlates of the five IBMH components using neuroimaging methods.
