Abstract

This article aimed to study: (1) the concept of stress from a Buddhist perspective, (2) Buddhist principles applicable to stress reduction, and (3) a synthesized Buddhist stress reduction model for Thai society. The research employed a qualitative documentary methodology, using Buddhist philosophy and holistic well-being theories as the research framework. The target sources comprised 40 academic documents and research articles published between 2018 and 2023, selected through purposive sampling. The research instruments included: (1) a document analysis form, (2) an expert interview form, and (3) a credibility verification form. Data were analyzed using content analysis and conceptual synthesis.

The research results were found as follows. 1. From a Buddhist perspective, stress originates from craving (tanhā) and attachment (upādānа), which are identified as the root causes of mental suffering (dukkha). 2. Buddhist principles effective for stress reduction include mindfulness (sati), clear comprehension (sampajjañña), mindfulness of breathing (ānāpānasati), loving-kindness meditation (mettā-bhāvanā), and contemplation of the Three Characteristics of Existence (tilakkhaṇa). 3. The Buddhist Stress Reduction (BSR) Model consists of four components: Awareness (rū'thān), Letting Go (plɔɔiwāng), Cultivating Loving-kindness (mettā-bhāvanā), and Developing Wisdom (paññā-bhāvanā). These findings are consistent with Attarung (2023), who demonstrated that Buddhist principles constitute a comprehensive framework for mental healing within Thai socio-cultural contexts.

Keywords: Stress, Buddhism, Stress reduction, Mindfulness, Well-being

Introduction

Stress has become one of the defining health challenges of contemporary society. The World Health Organization (2022) identifies stress as a major contributor to mental disorders, cardiovascular disease, and immune dysfunction globally. In Thailand, national surveys indicate that working-age adults report increasingly high levels of occupational and financial stress, with the Department of Mental Health (2023) documenting a significant rise in stress-related consultations following the COVID-19 pandemic. Conventional stress management approaches, including pharmacotherapy and cognitive-behavioral interventions, have demonstrated efficacy but remain limited in their cultural resonance for Thai Buddhist populations, for whom spiritual frameworks are central to meaning-making and coping.

Buddhism, as Thailand's predominant spiritual tradition, offers a philosophically rich account of the origin and resolution of psychological distress. The Buddha's teaching of the Four Noble Truths explicitly addresses suffering — its nature, its causes, and the systematic path to its cessation — providing a diagnostic and therapeutic framework with direct relevance to modern understandings of stress. Attarung (2023) demonstrated that Buddhist principles constitute a comprehensive system of mind healing applicable to contemporary mental health care. Building on this foundation, the present study focuses specifically on the application of Buddhist wisdom to stress reduction, arguing that Buddhist teachings offer both explanatory and practical resources that are underutilized in current clinical and community health practice.

This article employs a qualitative documentary research design to systematically examine Buddhist perspectives on stress and synthesize a practical model for stress reduction. The study is organized as follows: first, it examines the Buddhist conceptualization of stress; second, it identifies specific Buddhist principles and practices effective for stress reduction; and third, it proposes a four-component Buddhist Stress Reduction (BSR) Model. It is hoped that this contribution will support mental health practitioners, counselors, and community health workers in developing culturally grounded, spiritually sensitive stress management programs.

Research Objectives

1. To examine the concept of stress from a Buddhist perspective.
2. To analyze Buddhist principles applicable to stress reduction.
3. To synthesize a Buddhist Stress Reduction (BSR) Model for Thai society.

Literature Review

1. Buddhist Conceptualization of Stress. In Buddhist teaching, the closest equivalent to the modern concept of stress is dukkha, typically translated as suffering, unsatisfactoriness, or dis-ease. The Pali texts describe three dimensions of dukkha: ordinary suffering (dukkha-dukkha), the suffering of change (viparīnāma-dukkha), and the suffering of conditioned existence (saṅkhāra-dukkha). Modern stress research parallels these dimensions in distinguishing acute stress reactions, stress arising from loss and transition, and chronic existential anxiety (Kabat-Zinn, 2019). The Second Noble Truth locates the origin of suffering in craving (tanhā) — the desire for pleasant experience, the aversion to unpleasant experience, and the craving for existence itself. This teaching anticipates contemporary cognitive models identifying appraisal processes and attentional biases as central mechanisms of stress (Mongkolsuk, 2023).

2. Buddhist Practices in Contemporary Stress Research. The past three decades have produced substantial empirical evidence for the effectiveness of Buddhist-derived practices in stress reduction. Kabat-Zinn's (2019) Mindfulness-Based Stress Reduction (MBSR) program, grounded in Buddhist mindfulness meditation, has been extensively validated in reducing psychological and physiological stress responses. Goleman and Davidson (2020) documented that regular meditation practice produces lasting changes in stress-related neural circuits, including reduced amygdala reactivity and enhanced prefrontal regulation. In Thailand, Srisuk (2022) demonstrated that loving-kindness meditation significantly reduces anger and emotional arousal — key components of the stress response — among community samples. Saipetch (2023) further showed that Buddhist-integrated mental health programs outperform standard care in reducing stress and improving subjective well-being among Thai participants.

3. Knowledge Gaps. Despite this body of evidence, existing research focuses predominantly on mindfulness-based techniques, with limited attention to the broader Buddhist therapeutic system. The role of wisdom (paññā) cultivation, ethical living (sīla), and loving-kindness (mettā) as components of a comprehensive stress reduction framework remains underexplored. Moreover, there is a lack of culturally contextualized models specifically designed for Thai Buddhist populations. Kittinannik (2023) argued that the effectiveness of Buddhist interventions is maximized when they are embedded within familiar cultural and religious frameworks rather than delivered as decontextualized techniques. The present study addresses these gaps by synthesizing a holistic, culturally situated Buddhist Stress Reduction (BSR) Model.

In summary, the literature confirms the theoretical and empirical relevance of Buddhist teachings to stress reduction while identifying the need for a more comprehensive and culturally grounded model. This study draws on the Four Noble Truths, the Noble Eightfold Path, and the theory of Dependent Origination (paṭicca-samuppāda) as its theoretical foundations, as these offer the most complete account of the causes and resolution of psychological distress..

Conceptual Framework

This study is a qualitative documentary research. The researcher formulated the research framework based on three Buddhist theoretical constructs: (1) the Four Noble Truths (ariyasacca), which provide a diagnostic-prescriptive model of suffering and its resolution; (2) the Noble Eightfold Path (aṭṭhangika-magga), which prescribes the comprehensive lifestyle and meditative practices leading to freedom from stress; and (3) the theory of Dependent Origination (paṭicca-samuppāda), which illuminates the causal chain linking craving, clinging, and psychological suffering. These Buddhist frameworks were integrated with contemporary stress theory (Lazarus & Folkman's transactional model) and holistic well-being models. The independent variable consists of Buddhist principles and practices. The process involves systematic documentary analysis and expert consultation. The dependent variable is the proposed four-component Buddhist Stress Reduction (BSR) Model.

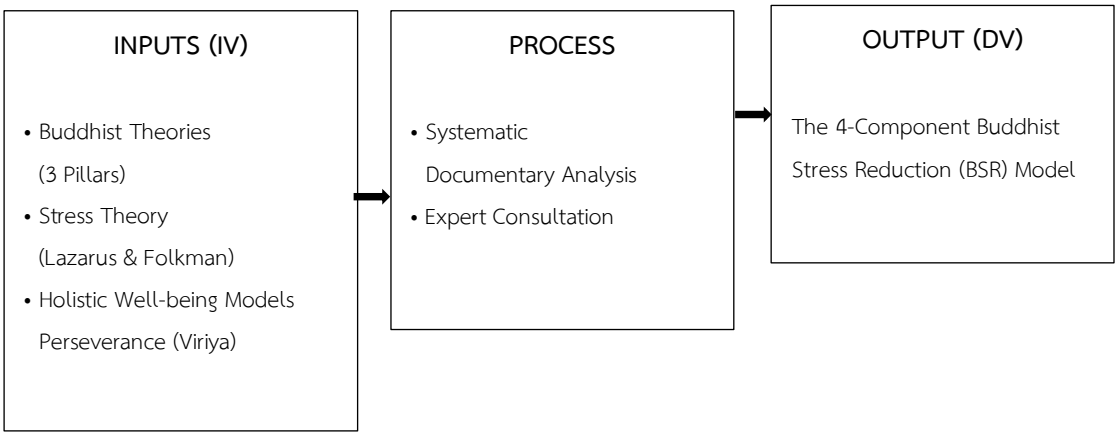

Figure 1. Research Framework

Research Methodology

Population and Sample

The population comprised all academic documents, research articles, Buddhist canonical texts, and expert opinions related to Buddhist approaches to stress and psychological well-being. The sample consisted of 40 purposively selected documents

published between 2018 and 2023, including peer-reviewed articles in psychiatry, psychology, and Buddhist studies; relevant sections of Pali canonical texts and commentaries; textbooks in stress management and integrative health; and official Thai health reports. Purposive sampling criteria required that sources directly address the intersection of Buddhist teaching and stress management, and meet predefined quality and relevance standards.

Research Instruments

Three research instruments were developed and validated. First, a document analysis form guided systematic extraction of theoretical constructs, key Buddhist principles, stress management strategies, and empirical findings from selected documents. Second, an expert interview form elicited insights from six specialists in Buddhist studies, clinical psychology, occupational health, and community health, using semi-structured interview questions. Third, a credibility verification form assessed the accuracy and applicability of synthesized content, reviewed by three independent experts.

Data Collection

Data collection occurred in three phases. Phase one involved systematic database searches in TCI Thai-Jo, PubMed, PsycINFO, and Google Scholar using keywords including "Buddhist stress reduction," "mindfulness and stress," "dukkha and mental health," and "Buddhist well-being." Phase two comprised individual semi-structured expert interviews conducted between February and April 2024, each lasting 60–90 minutes, audio-recorded with informed consent. Phase three involved submission of the synthesized BSR Model to the expert panel for credibility verification.

Data Analysis

Data were analyzed using content analysis and conceptual synthesis. Documentary data were coded thematically, with categories derived both deductively from the research objectives and inductively from the data. Expert interview transcripts were analyzed using thematic analysis. Methodological triangulation was achieved by cross-referencing documentary, interview, and theoretical data. The BSR Model was validated by the expert panel using a content validity index (CVI).

Research Results

Objective 1: Buddhist Conceptualization of Stress The documentary analysis established that Buddhist teaching conceptualizes stress as a manifestation of dukkha arising from the interaction of craving (tanhā), clinging (upādāna), and the conditions of

impermanent existence. The Pali Canon's account of Dependent Origination (paṭicca-samuppāda) traces a twelve-link causal chain through which ignorance (avijjā) gives rise to volitional formations, consciousness, and ultimately the full range of suffering. Applied to stress, this framework reveals that stress arises not from external events per se, but from the mind's habitual craving, aversion, and delusion in response to those events. This analysis aligns with Lazarus and Folkman's (1984) cognitive appraisal model, which locates stress in the interaction between person and environment, mediated by appraisal processes.

Expert informants unanimously affirmed that the Buddhist concept of dukkha provides a more comprehensive account of stress than the biomedical model, encompassing not only acute distress but also the pervasive background anxiety of conditioned existence. One expert from clinical psychology noted that Buddhist psychology's identification of craving and aversion as the primary stress-generating mechanisms is consistent with contemporary emotion regulation research, which highlights experiential avoidance and cognitive fusion as key drivers of chronic stress. Dhammapitaka (2023) supported this view, arguing that Buddhist psychology offers a causal account of mental suffering that is both philosophically rigorous and clinically actionable.

Objective 2: Buddhist Principles for Stress Reduction Five Buddhist principles were identified as particularly effective for stress reduction. First, mindfulness (sati) and clear comprehension (sampajjañña) interrupt the automatic stress-reactivity cycle by cultivating non-reactive awareness of stressors and stress responses. Santorelli et al. (2023) documented that MBSR, grounded in Buddhist mindfulness, significantly reduces salivary cortisol levels, perceived stress, and anxiety symptoms. Second, mindfulness of breathing (ānāpānasati) activates the parasympathetic nervous system, reducing physiological arousal and promoting emotional equilibrium (Goleman & Davidson, 2020). Third, loving-kindness meditation (mettā-bhāvanā) counteracts stress-amplifying emotions such as hostility, self-criticism, and social isolation. Srisuk (2022) demonstrated that loving-kindness practice significantly reduces anger and interpersonal stress among Thai community samples. Fourth, contemplation of impermanence (anicca) reduces catastrophizing by helping individuals recognize the transient nature of stressors, as supported by Sophaborn (2022). Fifth, ethical living (sīla) — specifically right speech, right action, and right livelihood — reduces stress arising from moral conflict, interpersonal friction, and occupational dissatisfaction (Phra Dhammakittiwoong, 2023).

Expert interviews corroborated and extended these findings. Informants emphasized that the combination of mindfulness, breathing practice, and loving-kindness constitutes the

most immediately accessible and clinically applicable cluster of Buddhist stress reduction techniques. One Buddhist studies expert noted that the Eightfold Path functions as a comprehensive lifestyle stress management system, addressing cognitive (right view, right intention), behavioral (right speech, right action, right livelihood), and meditative (right effort, right mindfulness, right concentration) dimensions of the stress response simultaneously.

Objective 3: The Buddhist Stress Reduction (BSR) Model Synthesizing documentary evidence and expert insights, the researcher proposes the Buddhist Stress Reduction (BSR) Model, comprising four interdependent components. Component 1: Awareness (Rūʼthān / Sati) — the cultivation of present-moment, non-judgmental awareness of stress triggers, physiological responses, and mental reactions. This component is operationalized through formal mindfulness meditation, mindfulness of breathing, and mindful daily activities. Awareness disrupts the automatic stress-reactivity cycle and creates the psychological space for intentional response.

Component 2: Letting Go (Plɔɔiwāng / Vossagga) — the deliberate release of craving, aversion, and clinging that fuel chronic stress. Operationalized through contemplation of impermanence (anicca) and insight meditation (vipassanā), this component enables individuals to disengage from stress-amplifying thought patterns and emotional reactivity. Component 3: Cultivating Loving-kindness (Mettā-bhāvanā) — the systematic development of benevolent goodwill toward oneself and others, countering the social isolation, self-criticism, and hostility that both arise from and amplify stress. Component 4: Developing Wisdom (Paññā-bhāvanā) — the progressive deepening of insight into the Three Characteristics of Existence, enabling a fundamental shift in one's relationship to stressors and a reduction in their long-term impact. These four components function as a mutually reinforcing cycle, with Awareness providing the entry point, Letting Go enabling disengagement from stress reactivity, Loving-kindness rebuilding positive emotional resources, and Wisdom producing lasting attitudinal change.

Discussion

Objective 1 Results. The finding that Buddhist teaching conceptualizes stress through the lens of Dependent Origination and craving-based suffering is consistent with Attarung's (2023) demonstration that Buddhist psychology provides a comprehensive causal account of mental distress. The parallel between Buddhist Dependent Origination and Lazarus and Folkman's appraisal model suggests that Buddhist teaching anticipates key insights of

contemporary stress psychology, lending theoretical coherence to Buddhist-integrated stress interventions. Dhammapitaka (2023) similarly argued that Abhidharma psychology constitutes a detailed science of mental causation that parallels and enriches modern cognitive neuroscience. This convergence strengthens the case for integrating Buddhist frameworks into clinical stress management.

Objective 2 Results. The identification of five Buddhist principles for stress reduction extends existing literature by moving beyond mindfulness to include loving-kindness, contemplation of impermanence, and ethical living as therapeutic mechanisms. Goleman and Davidson (2020) documented neurobiological evidence that long-term Buddhist meditation practice produces lasting reductions in stress-related brain activation. The present study adds to this literature by demonstrating the theoretical coherence of a multi-principle Buddhist approach that addresses cognitive, emotional, behavioral, and ethical dimensions of stress simultaneously. This finding resonates with the growing recognition in the stress literature that comprehensive, multi-component interventions are more effective than single-technique approaches (Williams et al., 2022; Hayes et al., 2022).

Objective 3 Results. The four-component BSR Model represents a significant advance over existing mindfulness-only approaches by providing a complete Buddhist stress management architecture. The inclusion of Letting Go (vossagga) directly addresses the craving and clinging identified as root causes of stress in Buddhist analysis, a mechanism absent from secular mindfulness programs. The emphasis on Loving-kindness (mettā) responds to evidence that social connection and self-compassion are powerful moderators of stress vulnerability (Srisuk, 2022). The inclusion of Wisdom (paññā) cultivation addresses the attitudinal foundation of long-term stress resilience, consistent with Sophaborn's (2022) finding that insight into impermanence reduces catastrophizing and promotes equanimity. Future empirical studies should test the BSR Model in randomized controlled trials with Thai adult populations experiencing occupational, family, and health-related stress.

New Knowledge Generated from the Research

The primary contribution of this research is the Buddhist Stress Reduction (BSR) Model, a theoretically grounded, culturally situated four-component framework for applying Buddhist wisdom to stress management. The BSR Model addresses the knowledge gap identified in the literature by integrating mindfulness, letting go, loving-kindness, and wisdom into a coherent, sequential, and mutually reinforcing healing process. This model can be visualized as a four-directional wheel (dhamma-cakka), where each spoke represents one component —

Awareness, Letting Go, Loving-kindness, and Wisdom — all turning around the central hub of the 'mind freed from craving' (citta-vimutti). The BSR Model can guide the development of structured Buddhist stress management programs in clinical settings, workplaces, schools, and community temples, and can inform the training of counselors, monks, and health workers working with stressed populations in Thai society.

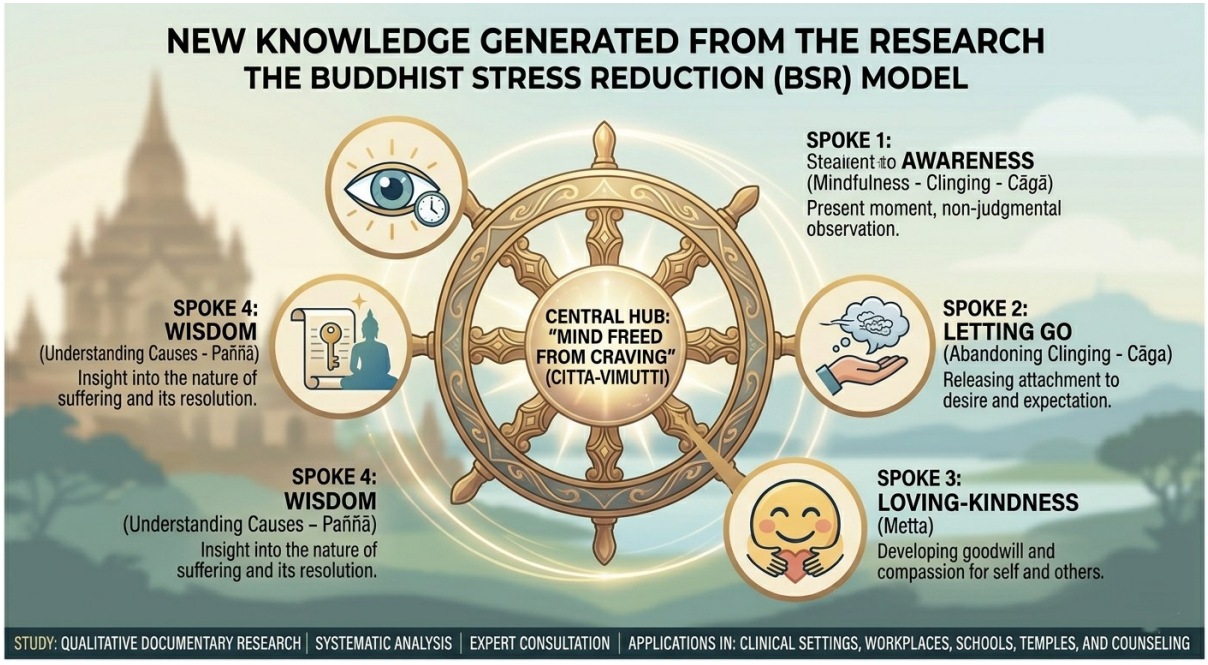

Figure 2: the Buddhist Stress Reduction (BSR) Model

Conclusion

This article has systematically examined Buddhist principles for stress reduction through qualitative documentary research. The findings demonstrate that Buddhist teaching provides a philosophically coherent and practically effective framework for understanding and managing stress. From the Buddhist perspective, stress arises from craving and clinging in the face of impermanent conditions, and is resolved through the cultivation of mindfulness, letting go, loving-kindness, and wisdom. The synthesized Buddhist Stress Reduction (BSR) Model offers a comprehensive, culturally grounded approach to stress management that complements and enriches conventional psychological interventions. Consistent with the foundational work of Attarung (2023) on Buddhist mind healing, this study affirms that Buddhist wisdom represents a valuable and underutilized resource for promoting mental well-being in Thai society and beyond.

Recommendations

1. Recommendations for Applying the Research Findings

Objective 1 finding: Stress originates from craving and clinging according to Buddhist teaching. Relevant public health agencies should incorporate Buddhist psychoeducation about the causes of stress into community mental health promotion campaigns, particularly in temple-based and school settings.

Objective 2 finding: Five Buddhist principles effectively reduce stress. Mental health and primary care practitioners should receive training in Buddhist-informed stress management techniques, including mindfulness of breathing, loving-kindness meditation, and contemplation of impermanence, and should be equipped to integrate these into standard counseling and health promotion practice.

Objective 3 finding: The BSR Model provides a comprehensive stress reduction framework. Hospitals, workplace health programs, educational institutions, and Buddhist organizations should collaborate to pilot, implement, and evaluate BSR-based stress management programs, with particular attention to high-stress populations including healthcare workers, teachers, and caregivers.

2. Recommendations for Future Research

The BSR Model can be applied across a wide range of clinical and community stress management contexts. Future research should: (1) conduct randomized controlled trials to validate the BSR Model with specific stressed populations including occupational stress, caregiver burden, and academic stress; (2) develop and validate standardized BSR program protocols, session guides, and outcome measures; (3) investigate neurobiological mechanisms underlying each BSR component using psychophysiological and neuroimaging methods; and (4) explore cross-cultural adaptations of the BSR Model for non-Buddhist and multicultural populations.
